

Research group of Ehud Meron

Physics-SEEP meeting, April 6, 2016

Research topics:

- Pattern formation in general
- Pattern formation in drylands
- Implications for ecosystem function

Mathematical aspects of pattern formation:

- Non-uniform instabilities of uniform states: studies of pattern dynamics using normal form equations
- Uniform instabilities resulting in multiple stable states: studies of front dynamics using singular perturbation theory
- Pattern control by periodic forcing in space and time

Spatial forcing of a stripe pattern

Temporal forcing of spiral waves

Pattern formation in drylands

Scaling up local processes and organism-level traits to landscape patterns and species assemblage properties by mathematical modeling:

$$\begin{aligned}\partial_t b &= G_b[w]b(1 - b/\kappa) - b + \nabla^2 b && \text{Areal biomass density} \\ \partial_t w &= Ih - Lw - G_w[b]w + \delta_w \nabla^2 w && \text{Soil-water content per unit ground area} \\ \partial_t h &= p - I(b)h - \nabla \cdot J \quad J = -2\delta_h h \nabla(h + \zeta) && \text{Surface-water height}\end{aligned}$$

Extension to community:

$$b = b(\mathbf{r}, t) \rightarrow b = b(\mathbf{r}, \chi, t)$$

Derive community-level properties:

Implications of pattern formation for ecosystem function

A population-level mechanism to survive water stress

Can mitigate adverse effects of desertification and biodiversity loss

Human intervention keeping ecological integrity high

Introduction

I Overview

II Pattern formation theory

III Applications to Ecology

Introduces the concepts and tools of pattern formation theory and demonstrates their utility in ecological research using problems from spatial ecology ...

Reviews:
